#### Abstract

In the present study, quantitative structure activity relationship study was performed on a series of novel quinazolinone derivatives as inhibitors of phosphodiesterase using chem. office ultra 7.0. Multiple linear regression analysis was performed to derive quantitative structure activity relationship models which were further evaluated internally as well as externally for the production of activity. The quantitative structure activity relationship evaluation involved a study on ten different models, most of them have shown $F$ value above 50. This study indicates that steric descriptors (logP, bend energy, molar refractivity, heat of formation and Henry's law) play important role for the activity. The data obtained from this present quantitative structure activity relationship study may be useful in the design of more potent substituted quinazolinone derivatives.

Key words: 2D-QSAR, quinazolinone, phosphordiesterase I inhibitor.

## INTRODUCTION

Parkinson's disease (PD) is a neurodegenerative disorder characterized by a myriad of symptoms that gradually decrease the quality of life of the patient. The first line of treatment is a dopamine replacement therapy with Levodopa[1]. Among other therapeutic strategies monoamine oxidase B (MAO-B) inhibitors have also been extensively used in PD[2]. In fact, selective MAO-B inhibitors (i.e., deprenyl and rasagiline) are currently used, alone or in combination with Levodopa, in the symptomatic treatment of Parkinson's disease. The side effects associated with the use of Deprenyl and, to a lesser extent, Rasagiline, likely due to their irreversible mechanism of inhibition, and the potential application of MAO-B inhibitors as anti-Alzheimer's agents are at
the moment the driving forces for the discovery of novel potent and selective MAO-B inhibitors[3,4].

Parkinson's disease ( PD ) is a chronic and progressive degenerative disease of the brain that impairs motor control, speech, and other functions. The risk of developing PD is dramatically increased with age, and symptoms often appear after the age of 50 . Current research indicating that 1 in 100 individuals over 60 has PD.

The quinazolinone moiety is a building block for approximately 150 naturally occurring alkaloids and drugs[5]. The natural quinazolinones and their synthetic analogs possess a variety of biological activities, including PDE inhibitory activity, anticonvulsant, bronchodilator, antiinflammatory, antimalarial, antituberculous, anti-HIV, narcotic antagonist, anti-tumor, tyrosine kinase inhibitor, adenosine antagonist, antimicrobial etc. Along with these activities, quinazoline derivatives showed a very prominent activity in PD.

QSAR studies have been widely used to understand the relationship between the structure of the molecule and biological activity. In the present study, QSAR analysis of some substituted quinazolinone derivatives with phosphodiesterase inhibitory property was performed by using multiple linear regression analysis. QSAR studies of these molecules have not been performed earlier. It was interesting to perform QSAR analysis using Chem Office 7.0 and correlate various physiochemical parameters to the activity for the design of some quinazolinone derivatives [Fig $1]$.

Fig 1

## MATERIALS AND METHODS

## Experiments:

A data set of 36 compounds has been taken from published article[6] (Laddha S.S and Bhatnagar S.P). The various descriptors studied are shown in Table 1. The values of $\mathrm{PIC}_{50}$ have been considered for computational work. All structure of these quinazolinone derivatives were constructed using ChemDraw and transferred to Chem 3D to convert them in to 3D structures. The energy minimization of the molecules was done using MM2 force field followed by semi empirical AMI (Austin model) Hamiltonian method available in MOPAC module by fixing root mean square gradient as 0.1 and $0.0001 \mathrm{kcal} / \mathrm{mol}$. Most stable structure for all the compounds was generated and used for calculating various thermodynamic, steric and electronic descriptors. Values of descriptors with their equation are shown and the values of observed and predicted activity are shown in Table II. All the calculated descriptor values were considered as independent variable and biological activity as dependent variable. INSTAT software was used
to generate QSAR models by multiple linear regression analysis. Cross validation was performed using leave-one method. Statistical measures used were: n-number of moles in regression, $\mathrm{r}^{2}$-correlation-coefficient, F-test (Fischer's value) for statistical significance, S-standard deviation.

Table 1: Descriptors considered for the QSAR study:

| S.No | Descriptor | Type |
| :---: | :---: | :---: |
| 1 | Heat of formation (HF) | Thermodynamic |
| 2 | Boiling Point (BP) | Thermodynamic |
| 3 | Critical Pressure (CP) | Thermodynamic |
| 4 | Critical Temperature (CT) | Thermodynamic |
| 5 | Critical Volume (CV) | Thermodynamic |
| 6 | Henry's Law constant (H) | Thermodynamic |
| 7 | Ideal Gas Thermal Capacity (IGTC) | Thermodynamic |
| 8 | LogP | Thermodynamic |
| 9 | Melting Point (MP) | Thermodynamic |
| 10 | Molar Refractivity (MR) | Thermodynamic |
| 11 | Standard Gibbs Free Energy (SGFE) | Thermodynamic |
| 12 | Connolly Accessible Area (SAS) | Steric |
| 13 | Connolly Molecular Area (CMA) | Steric |
| 14 | Connolly Solvent-Excluded Volume (SEV) | Steric |
| 15 | Ovality (OVA) | Steric |
| 16 | Principal Moment of Inertia - X (PMI-X) | Steric |
| 17 | Principal Moment of Inertia - Y (PMI-Y) | Steric |
| 18 | Principal Moment of Inertia - Z (PMI-Z) | Steric |
| 19 | Dipole Moment (D) | Electronic |
| 20 | Dipole Moment - X Axis (DX) | Electronic |
| 21 | Dipole Moment - Y Axis (DY) | Electronic |
| 22 | Dipole Moment - Z Axis (DZ) | Electronic |
| 23 | Electronic Energy (EE) | Electronic |
| 24 | HOMO Energy (HOMO) | Electronic |
| 25 | LUMO Energy (LUMO) | Electronic |
| 26 | Repulsion Energy (RE) | Electronic |
| 27 | Bend Energy ( $\mathrm{E}_{\mathrm{b}}$ ) | Thermodynamic |
| 28 | Charge - Charge Energy (CCE) | Thermodynamic |
| 29 | Charge - Dipole Energy (CDE) | Thermodynamic |
| 30 | Dipole - Dipole Energy (DDE) | Thermodynamic |
| 31 | Non-1,4 VDW Energy ( $\mathrm{E}_{\mathrm{v}}$ ) | Thermodynamic |
| 32 | Stretch Energy (SE) | Thermodynamic |
| 33 | Stretch-Bend Energy (SEE) | Thermodynamic |
| 34 | Torsion Energy ( $\mathrm{E}_{\mathrm{t}}$ ) | Thermodynamic |
| 35 | Total Energy (E) | Thermodynamic |
| 36 | Van der Waals 1,4 Energy (VDWE) | Thermodynamic |

## RESULTS AND DISCUSSION

The QSAR model was performed on ten different models and the results have been verified. Out of all the models studied Models IV comprising of Henry's law constant, $\log \mathrm{P}$, molar refractivity, ovality, partition co-efficient, shape attribute and critical pressure has been found to be extremely significant showing the importance of these descriptors in the designing of novel quinazolinone analogs for phosphodiesterase inhibitory activity, all other models were also found to be very significant emphasizing the importance of understanding various physicochemical parameters while designing a molecule to be potentially effective.

## CONCLUSION

This QSAR study has shown that the descriptors Henry's law constant, $\log$ P, molar refractivity, ovality, partition co-efficient, shape attribute and critical pressure play a vital role in imparting the biological property. This study has also shown that the biological activity is governed by various thermodynamic, steric and electronic descriptors. The models provide a brief insight in to the mechanism of action of these compounds. All these parameters can be considered for further designing of newer molecules for phosphodiesterase inhibitory activity.
