Abstract

Choledochal cysts are an uncommon inherent cystic dilatation of normal biliary conduit. The most well-known pre-birth analyzed structure type-I (85%-90%), comprises of fusiform enlargement of the normal bile conduit. There is correspondence between the bile pipe and the growth. In antenatal period finding might be made by the presence of a growth in the upper right half of the fetal mid- region on ultrasound. To separate it with other cystic sores pre-birth ultrasonography (USG), three-dimensional USG and attractive reverberation imaging might be useful. By early determination and brief evacuation of growth in post pregnancy period long haul entanglements like advancement of biliary cirrhosis, entryway hypertension, calculi development or adenocarcinoma can be stayed away from in later life. The employable mortality is around 10%. We are revealing an instance of antenatal determination type I inborn choledochal blisters at 21 weeks, its development and fruitful post pregnancy the board..
