Bioprospecting Endophytic Fungi *Cladosporium* genus as Source of Bioactive Metabolites

Ruby Bhullar Garcha

James Hind Institute, India

Abstract

The genus Cladosporium is of great interest to researchers due to its cosmopolitan distribution, large bio-diversity encompassing both phylogenetically and morphologically distinct, and enclosed against numerous morphologically similar but distinct genera. Cladosporium sp. is a common fungal endophyte of incredible ecological adaptability with wide applications in the field of agriculture as biocontrol agents, biostimulants aiming towards sustainable agriculture with a great diversity of secondary metabolites reported for wide implication in pharmaceutical science as antimicrobial, antineoplastic, and antiviral activities. Thus, better understanding and knowledge of the metabolites and compounds including various groups of human pathogenic species and heat-resistant fungi directs to biotechnological exploitation whether from terrestrial or marine environment towards crop improvement and also as a potential therapeutic agent. This work aimed at studying and analyzing the relationships among biodiversity and chemo-diversity in the context of future bioprospecting of Cladosporium genus from genomics to metabolomics with the emerging technologies and use of computational tools. The vast number of taxa comprising about 772 names (valid, invalid, legitimate, illegitimate species) in Cladosporium genus needs to be explored for the diverse applications which may lead to the discovery of novel compounds of antimicrobial activity, anticancer potential, Insecticidal activity, and also as a plant growth stimulant. This review comprehensively highlights the bioactive potential and benefits of metabolites produced by Cladosporium sp. more specifically novel species isolated from indoor as well outdoor environmental sources. The unique findings of Cladosporium species could revolutionize food production on earth as well in the artificial media in spaceflight as strains like TC09 are not known to cause disease in plants, humans, or animals and let plants grow as fast as a weed. The future studies are needed to understand the role of volatiles in Cladosporium species that accelerates crop plants' growth, and also to grow food on long-distance space voyages of the future with further research on interactions between the bioactive metabolites of endophytic fungi and host plant is necessary to explore for application in the field of agriculture and medicine by collaborating in context to research on agro ecology.

Biography

Ruby Bhullar Garcha has experience in research on Biofuels, with skill in CRISPR basics, Advance CRISPR, Medical Coding, Molecular Docking, passion in research, and writing. Her research-oriented, re-skill, up-skill approach, led her to take initiative to learn more on mitigating challenges faced by the World, among them one is sustainable agriculture for an evergrowing population.
