#### Abstract

6-phenylpteridine-2,4,7-triamine (Triamterene) is used in the treatment of edema associated with congestive heart failure. Conformational analysis and geometry optimization of triamterene was performed according to the HartreeFock (HF) calculation method by ArgusLab 4.0.1 software. Heat of Formation of procarbazine was 764.8268 $\mathrm{kcal} / \mathrm{mol}$, the steric energy calculated for procarbazine was 0.05130821 a.u. ( $32.19641689 \mathrm{kcal} / \mathrm{mol}$ ) and SCF energy was found to be -108.6545111064 au( $-68181.7966 \mathrm{kcal} / \mathrm{mol})$, which isthe most feasible position for the drug to interact with the receptor.

Key words: Triamterene, Molecular mechanics, Arguslab software.

## INTRODUCTION

6-phenylpteridine-2,4,7-triamine (Triamterene) is used in the treatment of edema associated with congestive heart failure, cirrhosis of the liver and the nephrotic syndrome[1]. Triamterene has a unique mode of action; it inhibits the reabsorption of sodium ions in exchange for potassium and hydrogen ions at that segment of the distal tubule under the control of adrenal mineralocorticoids (especially aldosterone)[2]. Triamterene occasionally causes increases in serum potassium which can result in hyperkalemia[3]. Molecular surface charges of drugs determines the level of interaction of the drugs with the receptor, these charges are partial atomic charges obtained from calculations carried out by the methods of computational chemistry which can be used to characterize the electronic charge distribution in a molecule and the bonding, antibonding, or nonbonding nature of the molecular orbitals for particular pairs of atoms[4-6] . To develop the idea of these populations, a real, normalized molecular orbital composed from two normalized atomic orbitals is taken into consideration by calculating the density matrix terms. From this calculations the difference between the number of electrons on the isolated free atom, and the gross atom population gives the values of the mullekan charges[7-8] . ZDO charges can also be generated from Argus lab using the AM1 parameterized method. In the zero deferential overlap (ZDO) approximation, the product of two deferent atomic orbitals is set to zero. The integral which survives the ZDO approximation was partly computed using the uniform charge sphere and the rest parameterized. The energies computed by molecular mechanics are usually conformational energies[9]. This means that the energy computed is meant to be an energy that will reliably predict the deference in energy from one conformation to the next.

## MATERIALS AND METHODS

All conformational analysis (geometry optimization) study was performed on a window based computer using Argus Lab 4.0.1, molegro molecular viewer and ACD Lab Chem Sketch software. Triamterene structure was sketched with ACD Lab Chem Sketch software and saved as MDL molfiles (*mol). The 6-phenylpteridine-2,4,7triamine (Triamterene) structure was generated by Argus lab, and minimization was performed with UFF molecular mechanics method [10-12] . The minimum potential energy was calculated by using geometry convergence function
in Argus lab software. Surfaces created to visualize ground state properties as well as excited state properties such as orbital, electron densities, electrostatic potentials (ESP), spin densities and generated the grid data used to make molecular orbital surfaces to visualize the molecular orbital and making an electro static potential mapped on electron density surface. The minimum potential energy was calculated for Triamterene through the geometry convergence map. Mulliken Atomic Charges, ZDO Atomic Charges of Triamterene and Ground State Dipole of 6-phenylpteridine-2,4,7-triamine (Triamterene) were determined using AM1/RHF method when the net charge was -1 and valence electrons 84 .

## RESULTS AND DISCUSSION

Prospective view and calculated properties of 6-phenylpteridine-2,4,7-triamine (Triamterene) molecule are shown in figure1. Figure 5 shows Electrostatic potential of molecular ground state mapped onto the electron density surface for the ground state The colour map shows the ESP energy (in hartrees) for the various colours. The red end of the spectrum shows regions of highest stability for a positive test charge, magenta/ blue show the regions of least stability for a positive test charge. The active conformation of Triamterene by molegro molecular viewer software is shown in figure 2. Figure 3 and 4, shows the highest occupied molecular orbital and the lowest unoccupied molecular orbital of Triamterene molecule.

Fractional coordination of triamterenemolecule is given in Table1, bond length and bond angles of triamterene are given in table 2 and 3 respectively, which are calculated after geometry optimization of molecule from ARGUS LAB by using molecular mechanics calculation. Table 5 shows calculated steric energy of Triamterenemolecule. Table 4 shows the ZDO and mullekan atomic charges of Triamterene. The steric energy and heat of formation calculated for Triamtereneare $0.05130821 \mathrm{a} . u$. ( $32.19641689 \mathrm{kcal} / \mathrm{mol}$ ) and $764.8268 \mathrm{kcal} / \mathrm{mol}$ respectively. SCF energy was found to be $-108.6545111064 \mathrm{au}(-68181.7966 \mathrm{kcal} / \mathrm{mol})$ as calculated by RHF/AM1 method, as performed by ArgusLab 4.0.1 suite.

## CONCLUSION

The present work indicates that the best conformation of triamterene is found to be at -108.6545111064 au ($68181.7966 \mathrm{kcal} / \mathrm{mol}$ ) which is the minimum potential energy by using Argus Lab software. At this point triamterene will be more active as a sodium ion reabsorption inhibitor. All geometric variables were completely optimized for triamterene and the lowest energy conformations were used in molecular modelling studies.
