Statement of the Problem

Bacterial biocontrol agents can improve plant health with various mechanisms. The bacterial genus *Lysobacter* includes different species producing compounds and lytic enzymes active against phytopathogenic microorganisms and therefore can be a source of new biocontrol agents. In particular, *L. capsici* AZ78 (AZ78), isolated from tobacco rhizosphere, effectively controls the causal agent of grapevine downy mildew (*Plasmopara viticola*), thanks to the production of antibiotics. Since bacterial communities might modulate the antibiotic production of biocontrol agents, the aim of this research was to understand if grapevine phyllosphere bacteria could affect the antibiotic production of AZ78. To test the hypothesis, we used a simplified model system with a culturable phytopathogenic oomycete (*Pythium ultimum*).

Methodology & Theoretical Orientation:

47 bacterial strains were isolated from leaves of *Vitis vinifera* L. cv. Pinot gris and Goldtraminer, identified by 16S rDNA phylogenetic analysis and their impact on AZ78's inhibitory activity was assessed in vitro according to the experimental design described

Findings:

Most of the Gram-negative bacterial isolates were γ -Proteobacteria, while the Gram-positive isolates belonged to Actinobacteria and Firmicutes. None of the isolated strains showed an inhibitory activity against *P. ultimum*. Interestingly, most of them promoted AZ78 inhibitory activity. In particular *Pseudomonas* sp. L35 increased AZ78 inhibitory activity of the 29.6±0.95%, this can be related to a change in AZ78 gene expression triggered by the presence of the strain counts of *Bifidobacterium* and *Akkermansia* increased in the mucin agar carriers as a function of time.

Conclusion & Significance:

The interaction with the natural microbiota is an important factor to be considered in evaluating biocontrol agent's efficacy, because their inhibitory activity can be affected by the microbiota itself. To gain a full picture, additional studies are necessary, taking into account the plant response, as well as considering the variation in AZ78 gene expression

Biography:

Elisa Francesca Brescia has obtained her Bachelor's degree in Biology at the University of Torino in 2013. She decided to continue her studies at the University of Pavia, where in 2015 she obtained her Master's degree in Experimental and Applied Biology and, in November 2015, she gained a nine-month research fellowship about the study of the fungal community associated to different *Rubus* species. In 2016, she started the doctoral course at the PhD school "Agricultural Science and Biotechnology" of the University of Udine at the Edmund Mach Foundation of San Michele all'Adige (TN) concerning the interactions between plant-associated bacteria and biocontrol agents in different nutrient conditions. From August 2018 to February 2019 she was a visiting PhD student at the Technical

University of Vienna (Austria), where she carried out a part of her PhD project studying the compounds produced during microbial interactions.
