Abstract:

A novel flow sensor is presented to measure the flow rate within microchannels in a real-time, noncontact and noninvasive manner. This patented sensing technology can be further used in measuring a physical characteristic of a fluid in a microfluidic system. The sensing platform includes a microfluidic chip that has a thin deformable membrane that separates a microfluidic channel from a microwave resonator sensor. The membrane is deformable in response to loading from interaction of the membrane with the fluid. Loading may be fluid pressure in the channel, or shear stress or surface stress resulting from interaction of the membrane with the fluid. The deformation of the membrane changes the permittivity in the region proximate the sensor. A change in permittivity causes a change in the electrical parameters of the sensor, thereby allowing for a characteristic of the fluid, such as flow rate, or a biological or chemical characteristic, to be measured.

Biography:

Hamid Sadabadi is an entrepreneur and researcher in the field of Microfluidics, Lab-on-a-chip and sensors/biosensors. He has completed his PhD in microfluidic from Concordia University in Montreal. He is recipient of 8 prestigious awards/scholarships including Quebec Doctoral Merit Scholarship and University of Calgary Eyes High Postdoctoral Fellowship where he did his postdoc researches. He is the currently CTO of Wire-

less Fluidics, a sensing technology development start-up. He has published more than 12 US patents, book chapters, and more than 16 papers in reputed journals.
