Scytosiphon lomentaria (Lyngbye) Link has Both Hypoglycemic and Hypolipidemic Activity

Abstract

Scytosiphon lomentaria and Padina pavonica are the two members of the Phaeophyceae. Our study has reported that these two brown macroalgae exhibit the important biological potentials such as antioxidant, hypoglycemic and hypolipidemic activities. However, S. lomentaria exhibit potent antioxidant activities, it has been observed that P. pavonica has strong antioxidant potentials such as 251.56 ± 1.33 mg GA g⁻¹ dw total phenolic content, 70.50 ± 1.4% DPPH radical scavenging activity and 60.6 ± 1.6% bleaching activity. In addition to antioxidant potentials, the species have not displayed significant cytotoxicity at the administered doses on MCF-7. Nevertheless, the highest dose for P. pavonica (100 µg ml⁻¹) caused to moderate cell viability inhibition (43%). A meaningful IC₅₀ value could not be calculated for S. lomentaria. Many enzyme inhibition tests are commonly used as indicator for biological activities. Both P. pavonica and S. lomentaria have higher α- glucosidase enzyme inhibition potential than acarbose. The strong inhibition percentages of these cold methanol extracts (89 and 88%, respectively) indicate their hypoglycemic activity. The pancreatic lipase enzyme inhibition assay was used to evaluate the hypolipidemic potentials of these microalgae. P. pavonica have strongly inhibited this enzyme when compared to orlistate (93 and 95%, respectively). These results have figured out the medical and pharmaceutical potentials of these species.

Keywords: Scytosiphon lomentaria; Padina pavonica; Antioxidant activity; MCF-7; Alpha- glucosidase; Pancreatic lipase

Introduction

Marine microalgae are known to be functional foods in Asian countries [1-4]. Due to their beneficial natural potentials, seaweed extracts have also been investigated for their biological activities [5-7]. Their low lipid content, high polysaccharides content and rich natural minerals [8] could create healthy diets for consumers [4,9,10] or present natural and non-toxic substances for researchers [11]. Some disease such as diabetes or cardiovascular complications which have world- wide high incidence [12] require special treatments [13,14] and diets [15-19] with the aim of decrease the blood glucose and lipid level. Two member of Phaeophyceae, Scytosiphon lomentaria and Padina pavonica, have also had significant biological activities [1,20-25]. However, extraction studies of plants give complicated results depend on extraction conditions such as solvent, temperature and term [26], many natural compounds or molecules have already been identified [27-29] undergone their preclinical studies [30,31], even applied for patent [32]. This study focuses on antioxidant activities and enzyme inhibition potentials of these two microalgae.

Materials and Methods

Collection of macroalgal material

The samples of Scytosiphon lomentaria and Padina pavonica were collected Izmir Gulf, from March 2011 to March 2012. Specimens in the labelled plastic bags were approximately 0.5-1 kg wet weight and immediately transported to the laboratory in cooled containers. To remove sand and epiphytes, algal thalli were gently rinsed in seawater. Taxonomic identification was done in terms of their morphology. Specimens had been stored at -20°C until experiments begun. The voucher specimens are preserved in the Herbarium of Ege University.
Preparation of macroalgal extracts
Thalli were lyophilized and 1 g of powder was extracted with 10 mL of methanol by shaking in an orbital shaker at 300 rpm overnight at +4°C. Extracts were then centrifuged at 4000 rpm for 10 minutes and supernatants were collected. Collected supernatants were placed in orbital shaker and extraction was initiated again. This procedure had been repeated for 10 days. After 10 days of extraction/centrifugation cycle, solvent was removed by lyophilization and powders of the crude extracts were dissolved in DMSO (dimethyl sulfoxide; 10 mg crude extract per mL; Sigma-Aldrich, USA) to be stored at -20°C for further experiments.

Thin Layer Chromatography (TLC)
Extraction efficiency was roughly evaluated by thin layer chromatography. Crude macroalgal methanol extracts were dissolved in methanol (1 mg mL⁻¹). Individual samples were loaded four times on silica coated aluminium TLC plate as a dash. The solvent system of chloroform: ethyl acetate: methanol (5: 5: 1, v/v) was used and the dashes was visualized after dipping into hydrochloric acid/ methanol (1:9, v/v) and heating until they appeared as dark dashes.

Determination of DPPH radical scavenging activity
Radical scavenging activities of the species were measured using 2,2-diphenyl-1-picryl-hydrazyl (DPPH; Sigma-Aldrich, USA) radical (Sharma and Bhat). Briefly, 100 µL of 50 µM DPPH solution was added into 96- well plates containing 100 µl of sample (5 mg mL⁻¹) solutions or 100 µl of positive control ascorbate (10 µg mL⁻¹). After 30 minutes, the decline in absorbance was recorded at 520 nm against individual blank. All measurements were repeated at least for two times and mean absorbance values were used to evaluate results. The capability to scavenge the DPPH radical was calculated using the following equation:

Scavenging activity (%)=(Abs blank–Abs sample)/Abs blank × 100

Determination of total phenol content
The total phenolic contents (TPC) of algal samples were determined by using Folin- Ciocalteu assay (Zhang et al.) in 96-well plates. Methanol extracts (10 mg mL⁻¹) were loaded into 96-well plate containing 90 µl of deionized water and 10 µl 2N Folin-Ciocalteu’s reagent (Sigma-Aldrich, USA) in each well. Plates were incubated for 5 minutes at room temperature. After incubation 100 µl of sodium carbonate (7%) was added to each well. Plates were shaken in the dark at room temperature for 90 min. The absorbance of the formed color was measured at 750 nm. All measurements were repeated three times and mean absorbance values were used to evaluate results. A calibration curve of gallic acid (ranging from 0.010 mg mL⁻¹ to 200 mg mL⁻¹; Sigma-Aldrich, USA) was drawn, and the results were expressed as gallic acid (GA) mg equivalents’ ratio to dry weight (g).

Antioxidant activity in β-carotene/linoleic acid system
The β-carotene/ linoleic acid activities of samples were evaluated by β-caroten bleaching system with the minor modifications for 96-well plate (Zhang et al.). 8 µl linoleic acid (SIGMA: L1012) were pipetted into eppendorf containing 800 µl of β- carotene in chloroform (1 mg mL⁻¹) and added 80 µl of Tween 40. The chloroform was blown away by nitrogen flow. This mixture was pipetted slowly in 20 ml of distilled water with vigorous agitation to form an emulsion. 20 µl of blank (ethanol), positive control (BHA: Butyl- 4- hydroxyanisole) or samples (5 mg mL⁻¹) were loaded 96- well plate and added 200 µl of the emulsion and the absorbance was measured immediately at 450 nm. The plate was placed in a dark room for 90 min. The absorbance was measured again. All measurements were carried out in triplicate. The antioxidant activity of extracts was evaluated using the following formula:

AA (%)=[1-(A0- A90)/(A’0- A’90)] × 100

Where the A0 and A’0 are the absorbance values measured at zero time of the sample and the control, respectively, and A90 and A’90 are the absorbance values measured at 90 min of the sample and the control.

Cell culture
All studied cell lines were kindly provided by Ege University Medical School Department of Medical Oncology. Breast cancer cell line MCF-7 was cultured in RPMI medium (Lonza, CH) with 10% fetal bovine serum (Lonza, CH) and penicillin-streptomycin (100 U mL⁻¹; Sigma-Aldrich, USA) supplement. Immortalized mammary epithelial cell line MCF-10A was cultured in DMEM medium (Lonza, CH) supplemented with 10% fetal bovine serum (Lonza, CH), penicillin-streptomycin (100 U mL⁻¹; Sigma-Aldrich, USA), EGF (20 ng mL⁻¹) epidermal growth factor; New England Biolabs, USA), hydrocortisone (0.5 µg mL⁻¹; Biochrom, GER) and insulin (10 µg mL⁻¹; Sigma-Aldrich, USA). All cell lines were maintained in CO₂ incubator with standard incubation conditions. Cells were treated with different concentrations of macroalgal methanol extracts reconstituted in dimethyl sulfoxide (DMSO; Sigma-Aldrich, USA) and diluted with proper media for viability experiments. For each experimental procedure, appropriate concentration of vehicle (DMSO) was used as a carrier control.

Inhibition of cell viability
Growth inhibitory effects of extracts were investigated via mitochondrial dehydrogenase activity by WST-8 colorimetric assay kit (Sigma-Aldrich, USA). Briefly, MCF7 cells were seeded in 96- well plate 10 × 10³ cells per well and incubated overnight for both cell attachment and growth. Macroalgal extracts were added to wells in different final concentrations (0, 1, 5, 10, 25, 50 and 100 µg mL⁻¹) with six repeats. Maximum DMSO concentration was 1%. After 72 hours of incubation, 10 µl of WST-8 reagent was added to wells and plates were incubated at 37°C for 15 minutes for the formation of color. Absorbance was measured at 450 nm on multi-well spectrophotometer. Untreated cell viability was considered as 100% and extract- treated cell viabilities were calculated accordingly. IC₅₀ (inhibitory concentration 50) values were calculated using CalcuSyn v2.0.

Enzyme inhibiton tests
α- Glucosidase enzyme inhibiton: α- Glucosidase enzyme
inhibit test was used to determine the hypoglycemic activity of the macroagal extracts. This enzyme inhibition activity was assessed using the PNG (4- nitrophenil- α- D- glucopyranoside; SIGMA: N1377) as substrate and Saccharomyces cerevisiae α-glucosidase as enzyme (SIGMA: G5003). 50 µl of PBS (100 mM; pH 7.5) were loaded into wells of 96-well plate and 2 µl of samples (1 mg mL⁻¹), acarbose (250 mg mL⁻¹; as positive control) or PBS (for enzyme reaction) were added. 15 µl of α-glucosidase was added, except for blank. The plate was pre-incubated at 37°C for 10 min. 15 µl of PNG (3 mM) was added into wells and the plate was incubated at 37°C for 30 min. The enzymatic hydrolysis of substrate was monitored by the amount of p-nitrophenol released in the reaction mixture at 410 nm where the enzymes were replaced buffer. The inhibition percentage of α-glucosidase was assessed by following formula:

\[
\text{Inhibition (\%)} = \left(1 - \frac{Ae - As}{Ac}\right) \times 100
\]

Where the Ae is the absorbance value of enzyme reaction and as is the absorbance value of extract added reaction.

**Pancreatic lipase enzyme inhibition test:** Pancreatic lipase enzyme inhibition test was designed as fluorometric assay for 96-well plates (black flat bottom). 50 µl phosphate buffer with CaCl₂ (Ca-PBS; 0.1 mM CaCl₂, pH 7.5), 50 µl of pancreatic lipase (SIGMA: L0382; 2 mg mL⁻¹) were loaded into wells. 20 µl of sample (5 µg mL⁻¹) was pipetted into wells and the plate was incubated at 37°C for 30 min. The amount of 4-MU released by the lipase measured using a fluorescence spectrometer at an excitation wavelength of 320 nm and an emission wavelength of 450 nm. The inhibition percentage of pancreatic lipase was assessed by following formula:

\[
\text{Inhibition (\%)} = 100 - (\text{As} \times 100) / \text{Ac}
\]

Whereas is the absorbance value of extract added reaction, Ac is the absorbance value of enzyme reaction.

**Results and Discussion**

*Scytosiphon lomentaria* (Lyngbye) Link and *Padina pavonica* (Linnaeus) Thivy were collected with the Voucher IDs EGE41710 and EGE41834, respectively. Collection data about date, location and coordinates was presented in our previously study [33]. TLC profiles of macroagal cold methanol extracts are shown in Figure 1. The fingerprints exhibit the high abundance of extracted molecules for these macroagal samples. Our study has figured out high antioxidant, hypoglycemic and hypolipidemic potentials for cold methanol extracts for *Scytosiphon lomentaria* and *Padina pavonica*.

Antioxidant activities of macroagal extracts are presented in Table 1. Commonly named as peacock’s tail, *P. pavonica*, has 251.56 ± 1.33 mg GA g⁻¹ dw TPC, 70.50 ± 1.4% DPPH radical scavenging activity and 60.6 ± 1.6% bleaching activity. Whereas, in literature, other extractions types of *S. lomentaria* which had been used different solvent reported different DPPH inhibition rates such as 16.00 ± 1.13% for carbohydratic hydrolase and 19.33 ± 0.49 proteolytic enzyme extract [34]. It has been reported that its methanol: chloroform extract [35] and ethanol extract [1] have low DPPH scavenging capacities. It has also been observed that different solvents used for extraction of this species cause lower yield for TPC [35,36]. It is quite apparent that these differences of antioxidant activity probably arise from the different collection dates, performing drying and/or milling, solvent selection and extraction term. Based on the interactions of compound being analyzed and solvent, this situation is generally valid for all kind of extraction studies. According to our results, *P. pavonica* has displayed both high TPC and DPPH inhibition rates. But it has been reported that its methanol and ethanol extracts exhibit lower TPC and DPPH inhibition rate than those our study [37]. Some solvent but different yields for TPC probably are a result of the temperature. The colder temperatures during extraction protect the compounds of microalgae. As a summary, even if the parameters for the solvent type, the temperature and term of extraction are different, both *S. lomentaria* and *P. pavonica* have good antioxidant capacities.

The effects of macro algal extracts on viability of MCF-7 cells are depicted in Figure 2. At 100 µg ml⁻¹ of their concentrations, both *P. pavonica* and *S. lomentaria* weakly inhibited MCF-7 viability. At the lower doses than 100 µl ml⁻¹, *S. lomentaria* did not display a cell viability inhibition. While, IC₅₀ value of *P. pavonica* was 320 µg ml⁻¹, IC₅₀ value of *S. lomentaria* was not determined. The methanol extract has displayed cytotoxic activities on Hela (IC₅₀: 86.45 µg ml⁻¹) and MDA-MB-231 (IC₅₀: 74.59 µg ml⁻¹) cells line [38]. It has been reported that xenican diterpenes of *P. pavonica* methanol extract exhibits cytotoxicity on H460 cells (37.3%) and HepG2 cells (24.1%) at 10 µl ml⁻¹ concentration [39]. But, oxyester of *P. pavonica* dichloromethane extract inhibits the viability of KB cells.

![Cell viability inhibition potential of macroagal extracts on MCF-7 cells. Scytosiphon lomentaria, Padina pavonica.](image2)
with the percentage inhibition of 100% [20]. It is very clear that the solvent type, extraction conditions, extracted compound, administered doses and cell line selection affect the throughputs of cytotoxicity studies. An IC\textsubscript{50} value could not be determined for \textit{S. lomentaria}, in contrast our results, its ethanol: acetone fraction induced the apoptosis by way of the down-regulation of Bcl-2 and the activation of caspase on leukemia cells [21]. Both Padina pavonica and Scytosiphon lomentaria have higher \(\alpha\)-glycosidase enzyme inhibiton potential than acarbose. According to the measurements, positive control acarbose inhibited 79.5 percentage of \(\alpha\)-glucosidase enzyme activity. But, the inhibition rates of macroalgal extracts were higher than this value. In spite of the fact that both macroalgal extracts were subjected as crude material, \textit{P. pavonica} and \textit{S. lomentaria} strongly inhibited this enzyme, 89 and 88%, respectively. It has been observed that its polyphenols and phlorotannins could weakly inhibit \(\alpha\)-amylase and \(\alpha\)-glucosidase than acarbose [40]. Researchers have notified that its ethanol extract lead to ameliorate elevated levels of glucose, aspartate aminotransferase, lactate dehydrogenase and creatine kinase and decline serum insulin levels of Type 2 diabetic rats [41]. Experiments showed that \textit{S. lomentaria} also have same inhibition effect on this enzyme. This is the fact that both \textit{P. pavonica} and \textit{S. lomentaria} have strong-glycosidase inhibition potential is taxonomically important so that probably reflects seconder metabolite profile analogy.

### Conclusion

The pancreatic lipase enzyme inhibiton percentages for the methanol extracts \textit{P. pavonica} and \textit{S. lomentaria} were measured as 93 and 68%, respectively. Orlistat was used as a positive control (95.2%). Our study presents the first results about hypoglycemic and hypolipidemic activity of \textit{S. lomentaria} and hypolipidemic activity of \textit{Padina pavonica}. These species should be considered as sources for anti-diabetic and anti-hypolipidemic substances.

### Conflict of Interest

The authors declare that there are no conflicts of interest.
