

DISTAL CLAVICULE RESSECTION

Marcio Alberto de Lima Cavalcanti¹, Igel de Souza Aquino² and Daniel Brasil Araújo Nicolletti³

¹Instituto de Ortopedia e Traumatologia de Campina Grande-PB (IOT-CG), Brazil

²Hospital do Servidor Público Estadual, Brazil

³Hospital Getúlio Vargas, Brazil

The objective of this work was to compare the results of submitted patients the surgical treatment for osteoarthritis to acromio-clavicular, being comparative the results between the patients treated with Shoulder arthroscopy and for opened surgery. In the total 50 patients, being 25 for each group had been followed. We find an average UCLA of 31.9, being resulted excellent and good 88% of in group 1 and 96% in group 2, with average of 33.3. The scale of Constant also presented resulted similar, in the group 1 average of 60.3 and in group 2 of 62.1. When carried through the analysis statistics for the method of Wilcoxon comparing itself the results between groups 1 and 2 we met a $p < 0.05$, having significance statistics; the accompaniment time also was evaluated with the significant result statistical. We conclude that both techniques reach good results, when carried through correctly. However, in this first phase of the work, different of current literature, the results of the called surgeries opened had gotten better resulted, this can be credited to the biggest time of accompaniment of the patients of group 2 (58 months on average) when compared with the one of group 1 (34 months), to small number n of patients or to the curve of learning for accomplishment of the arthroscopy, considered method innovator and with only 3 decades of introduction in armamentarium surgical of the surgery of the Shoulder.

Biography
